

Compilers

Topic: Bottom-Up Parsing - LR(1) Parsers

Monsoon 2011, IIIT-H, Suresh Purini

ACK: Some slides are based on Keith Cooper's CS412 at Rice University

LR(1) Grammars

LR(1) – Reading the input string from left to right.

LR(1) – Deriving a right-most derivation for the string.

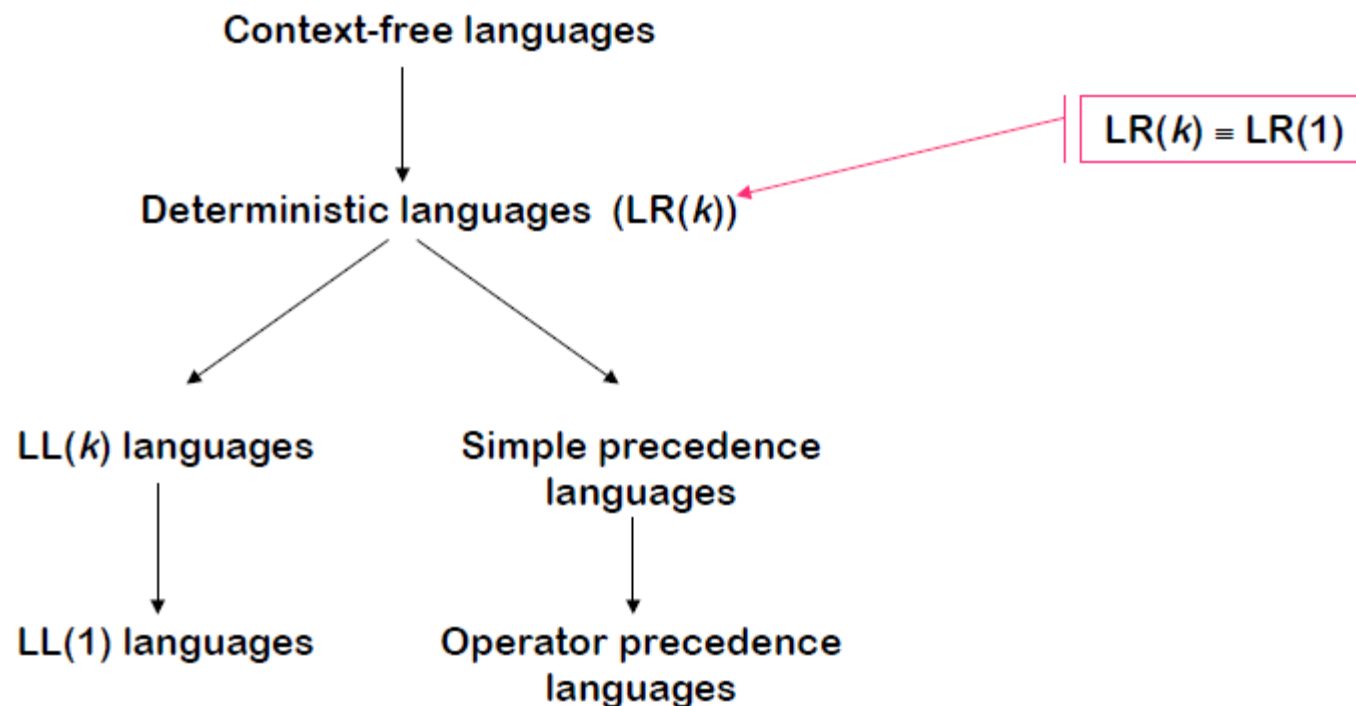

LR(1) – one token look-ahead

- **Intuitively:** For a grammar to be LR(1) it is sufficient that a left-to-right shift-reduce parser be able to recognize handles of right-sentential form when they appear on the stack.
- **Remark:** LR(k) and LR(1) grammars have the same expressive power. However, we could probably write a simpler LR(k) grammar for a language than an LR(1)

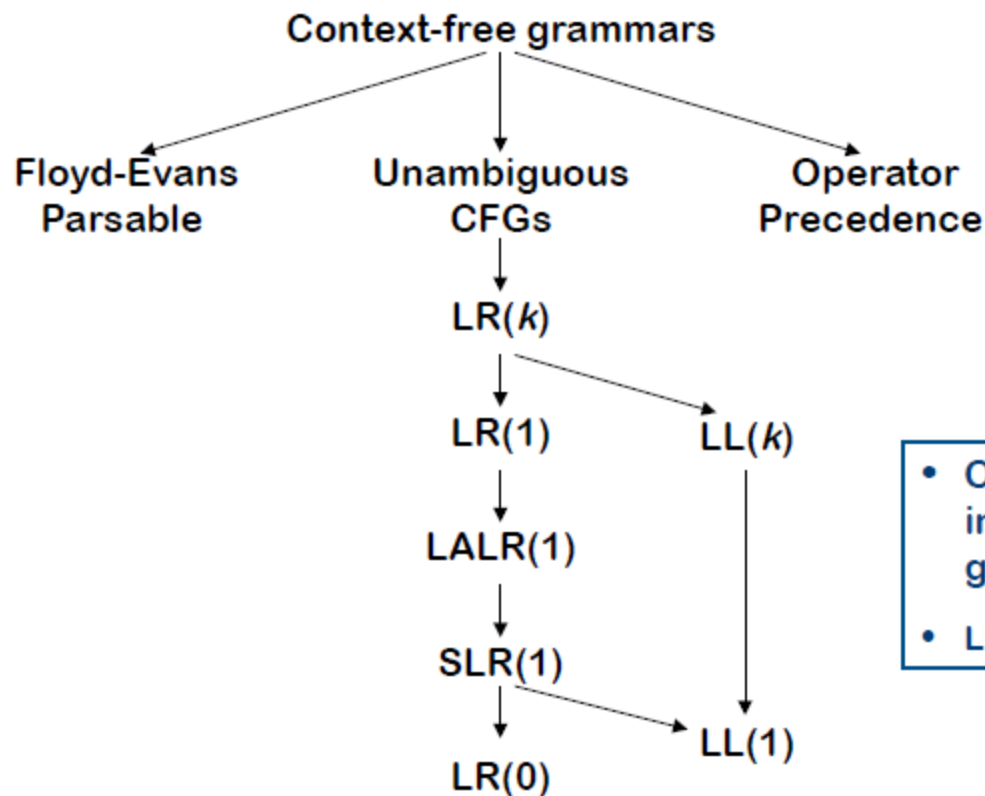

LR(1) Grammars

- Almost all programming language constructs are LR(1) Parsable
- LR-parsing method is the most general non-backtracking shift-reduce parsing method known.
- LR parser can detect a syntactic error as soon as it is possible to do so on a left-to-right scan of the input
- LR(1) Grammars are strictly more powerful than LL(1)

Hierarchy of Context-Free Languages

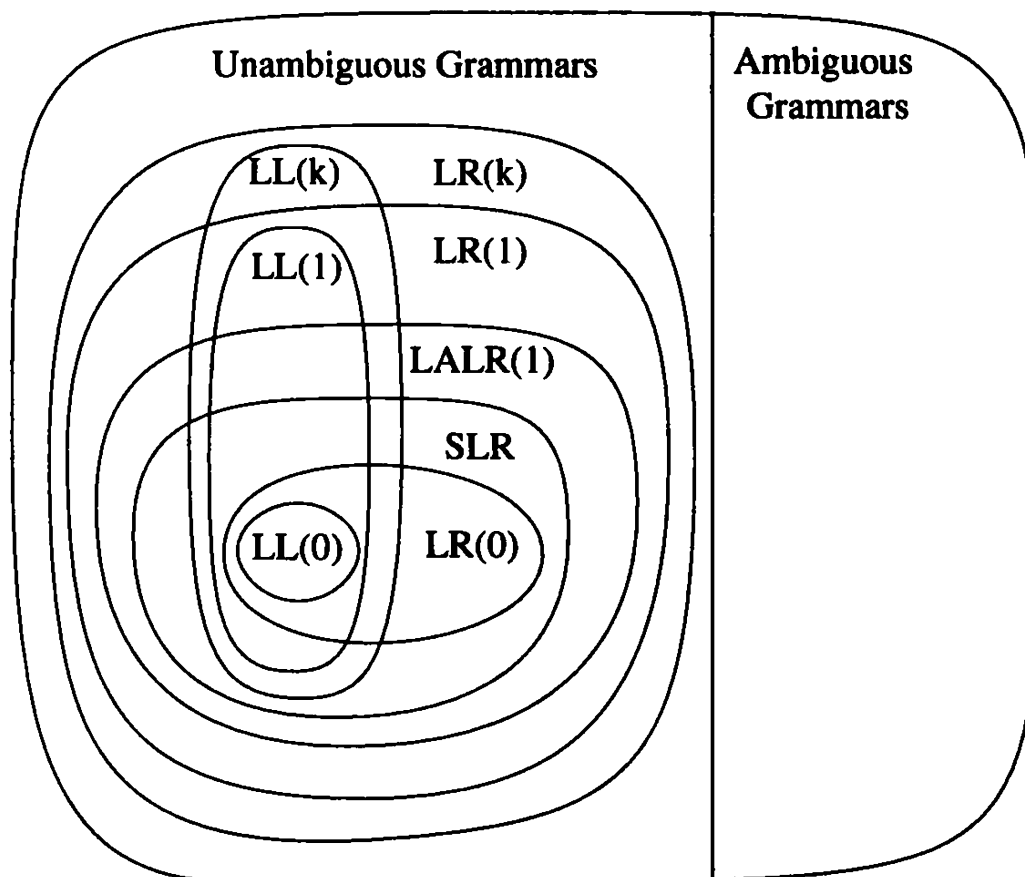

Hierarchy of Context-Free Languages

- Operator precedence includes some ambiguous grammars
- $LL(1)$ is a subset of $SLR(1)$

Hierarchy of Context-Free Languages

LR(k) versus LL(k)

Finding Reductions

- LR(k) – Each reduction in the parse is detectable with
 - the complete left context,
 - the reducible phrase, itself, and
 - the k terminal symbols to its right
- LL(k) – Parser must select the reduction based on
 - The complete left context
 - The next k terminals
 - Thus, LR(k) examines more context

LR(1) versus LL(1)

The following LR(1) grammar has no LL(1) counterpart

0	<i>Goal</i>	\rightarrow	<i>S</i>
1	<i>S</i>	\rightarrow	<i>A</i>
2			<i>B</i>
3	<i>A</i>	\rightarrow	(<i>A</i>)
4			<u><i>a</i></u>
5	<i>B</i>	\rightarrow	(<i>B</i> >
6			<u><i>b</i></u>

- It requires an arbitrary lookahead to choose between *A* & *B*
- An LR(1) parser can carry the left context (the '(' s) until it sees *a* or *b*
- The table construction will handle it
- In contrast, an LL(1) parser cannot decide whether to expand *Goal* by *A* or *B*
 - *No amount of massaging the grammar will resolve this problem*

LR(1) Item

Def: An LR(1) item is of the form $[A \rightarrow \alpha.\beta, a]$, where $A \rightarrow \alpha\beta$ is a production and **a** is either a terminal symbol or \$.

Grammar	Example LR(1) Items
$S \rightarrow L = R \mid R$	$[S \rightarrow . L = R, id]$ $[S \rightarrow L . = R, id]$
$L \rightarrow * R \mid id$	$[S \rightarrow L = . R, id]$ $[S \rightarrow L = R . , id]$
$R \rightarrow L$	$[L \rightarrow . * R, \$]$ $[L \rightarrow * . R, \$]$ $[L \rightarrow * R . , \$]$

LR(1) Sets of Items

Def: An LR(1) Set of Items I is a collection of LR(1) Items (nothing fancy here, just the usual set definition).

Examples:

1. $I_1 = \{ [S \rightarrow \cdot L = R, id], [S \rightarrow L = \cdot R, id] \}$
2. $I_2 = \{ [S \rightarrow L = \cdot R, id], [S \rightarrow L = R \cdot, id], [L \rightarrow * R \cdot, \$] \}$

$S \rightarrow L = R \mid R$

$L \rightarrow * R \mid id$

$R \rightarrow L$

Closure of LR(1) Items

Def: If I is the set of LR(1) items for a grammar G , then $\text{CLOSURE}(I)$ consists of

- Every item of I
- If $[A \rightarrow \alpha.B\beta, a]$ is in $\text{CLOSURE}(I)$ and $B \rightarrow \gamma$ is a production, then for each terminal b of $\text{FIRST}(\beta a)$, $[B \rightarrow \cdot \gamma, b]$ is also present in $\text{CLOSURE}(I)$.

Compute

- 1) $\text{CLOSURE}(\{ [S \rightarrow L \cdot = R, \$] \})$
- 2) $\text{CLOSURE}(\{ [L \rightarrow \cdot * R, =], [L \rightarrow * \cdot R, \text{id}] \})$
- 3) $\text{CLOSURE}(\{ [S \rightarrow \cdot L = R, \$] \})$

$S \rightarrow L = R \mid R$

$L \rightarrow * R \mid \text{id}$

$R \rightarrow L$

Algorithm for Computing CLOSURE(I)

```
SetOfItems CLOSURE( $I$ ) {  
    repeat  
        for ( each item  $[A \rightarrow \alpha \cdot B \beta, a]$  in  $I$  )  
            for ( each production  $B \rightarrow \gamma$  in  $G'$  )  
                for ( each terminal  $b$  in  $\text{FIRST}(\beta a)$  )  
                    add  $[B \rightarrow \cdot \gamma, b]$  to set  $I$ ;  
    until no more items are added to  $I$ ;  
    return  $I$ ;  
}
```

Computing GOTO(I,X)

- I is an LR(1) Set of Items and X is either a terminal, or a non-terminal, or \$ symbol i.e., $(X \in N \cup T \cup \{ \$ \})$.

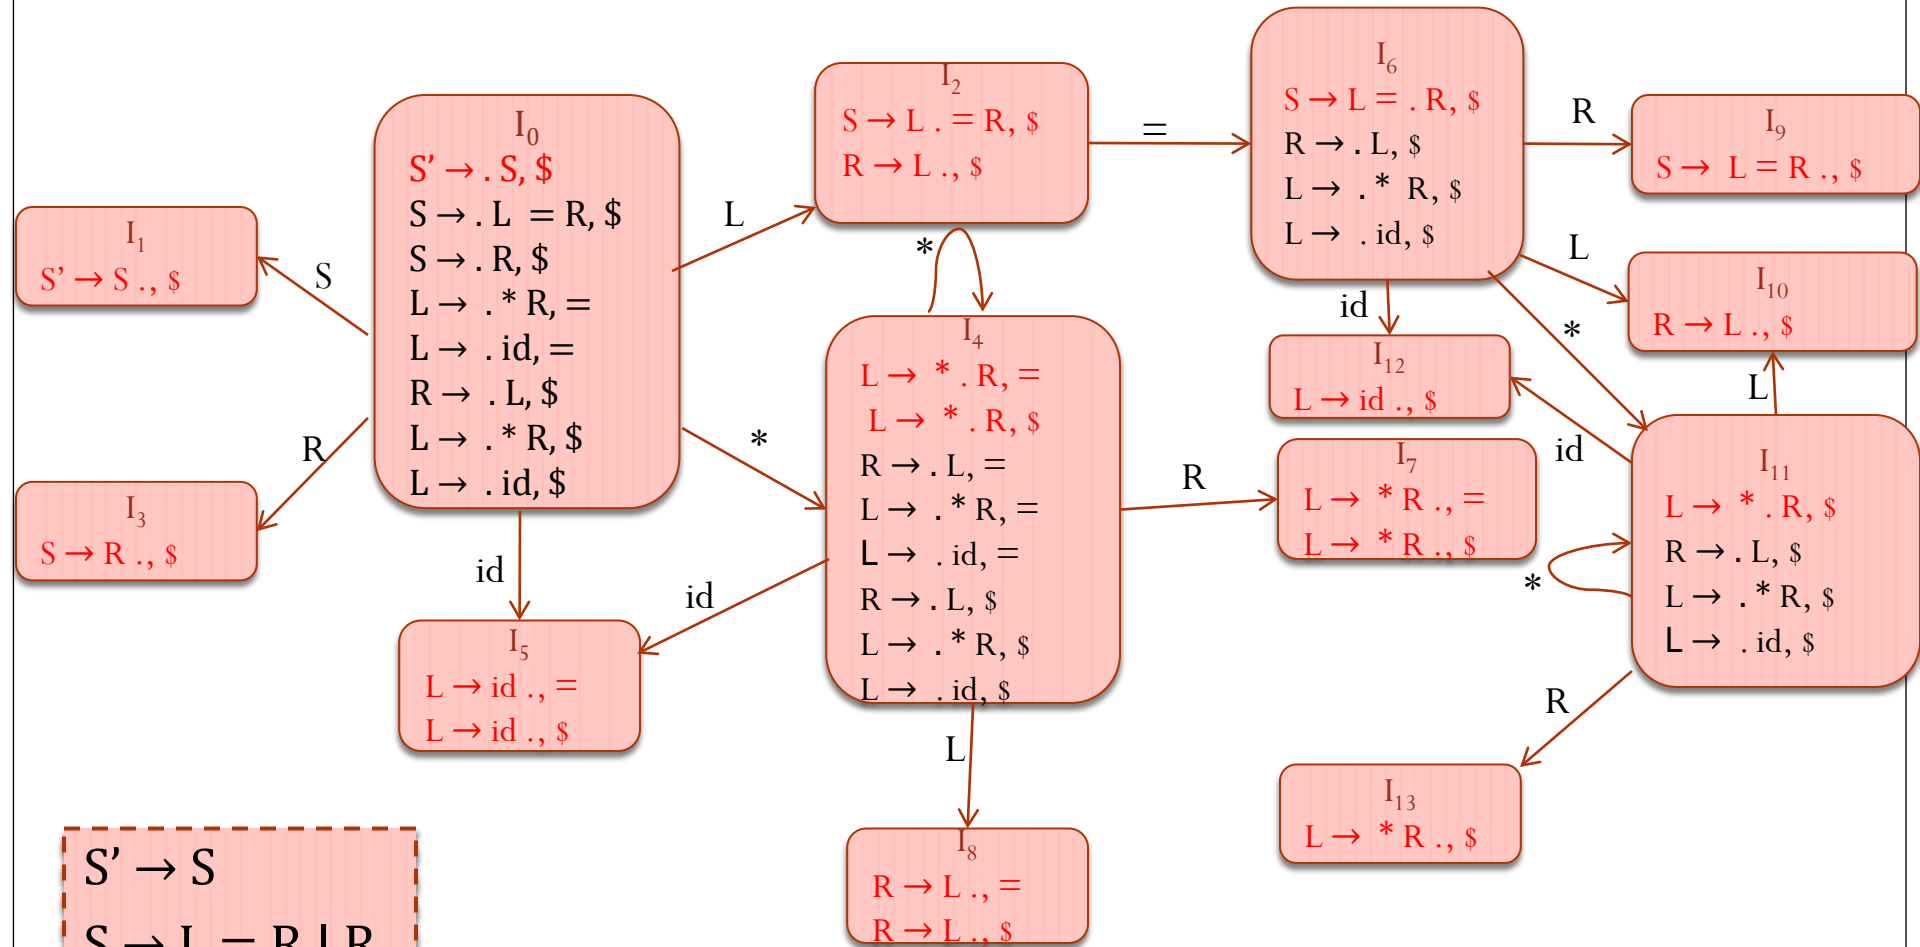

```
SetOfItems GOTO( $I, X$ ) {  
    initialize  $J$  to be the empty set;  
    for ( each item  $[A \rightarrow \alpha \cdot X \beta, a]$  in  $I$  )  
        add item  $[A \rightarrow \alpha X \cdot \beta, a]$  to set  $J$ ;  
    return CLOSURE( $J$ );  
}
```

Computing LR(1) Sets of Items in an LR(1) Automaton

```
void items( $G'$ ) {  
    initialize  $C$  to  $\text{CLOSURE}(\{[S' \rightarrow \cdot S, \$]\})$ ;  
    repeat  
        for ( each set of items  $I$  in  $C$  )  
            for ( each grammar symbol  $X$  )  
                if (  $\text{GOTO}(I, X)$  is not empty and not in  $C$  )  
                    add  $\text{GOTO}(I, X)$  to  $C$ ;  
    until no new sets of items are added to  $C$ ;  
}
```

Note: We have to augment the grammar with the production $S' \rightarrow S$ where S' is the new start symbol.

LR(1) Automaton

Note: LR(1) items marked in **Red** in each set are called kernel items. Non-kernel items can be derived from kernel items by applying a closure operation.

LR(1) Parsing Table Construction

Rules for constructing the Action Part of the LR(1) Parsing Table

1. If state i contains $[S' \rightarrow S ., \$]$, set $\text{ACTION}[i, \$]$ to **acc**.
2. If state i contains $[A \rightarrow \alpha.a\beta, b]$ and $\text{GOTO}(i, a) = j$, then set $\text{ACTION}[i, a] = \text{shift } j$.
3. If state i contains $[A \rightarrow \alpha., a]$, then set $\text{ACTION}[i, a]$ to “reduce $A \rightarrow \alpha$ ”.

Rules for constructing the GOTO Part of the LR(1) Parsing Table

1. For state i and non-terminal A if $\text{GOTO}(i, A) = j$, set $\text{GOTO}(i, A) = j$.
2. All the blank entries at the end are made “error”.
3. The state corresponding to the item $[S' \rightarrow . S]$ is the initial state.

LR(1) Parsing Table Construction

	Action Part				GOTO Part		
	*	=	id	\$	S	L	R
0	S4		S5		1	2	3
1				acc			
2		S6		R6	4	5	
3				R3			
4	S4					8	7
5		R5		R5			
6	S11		S12			10	9
7		R4		R4	8		
8		R6		R6			
9				R2			
10				R6			
11						10	13
12				R5			
13				R4			

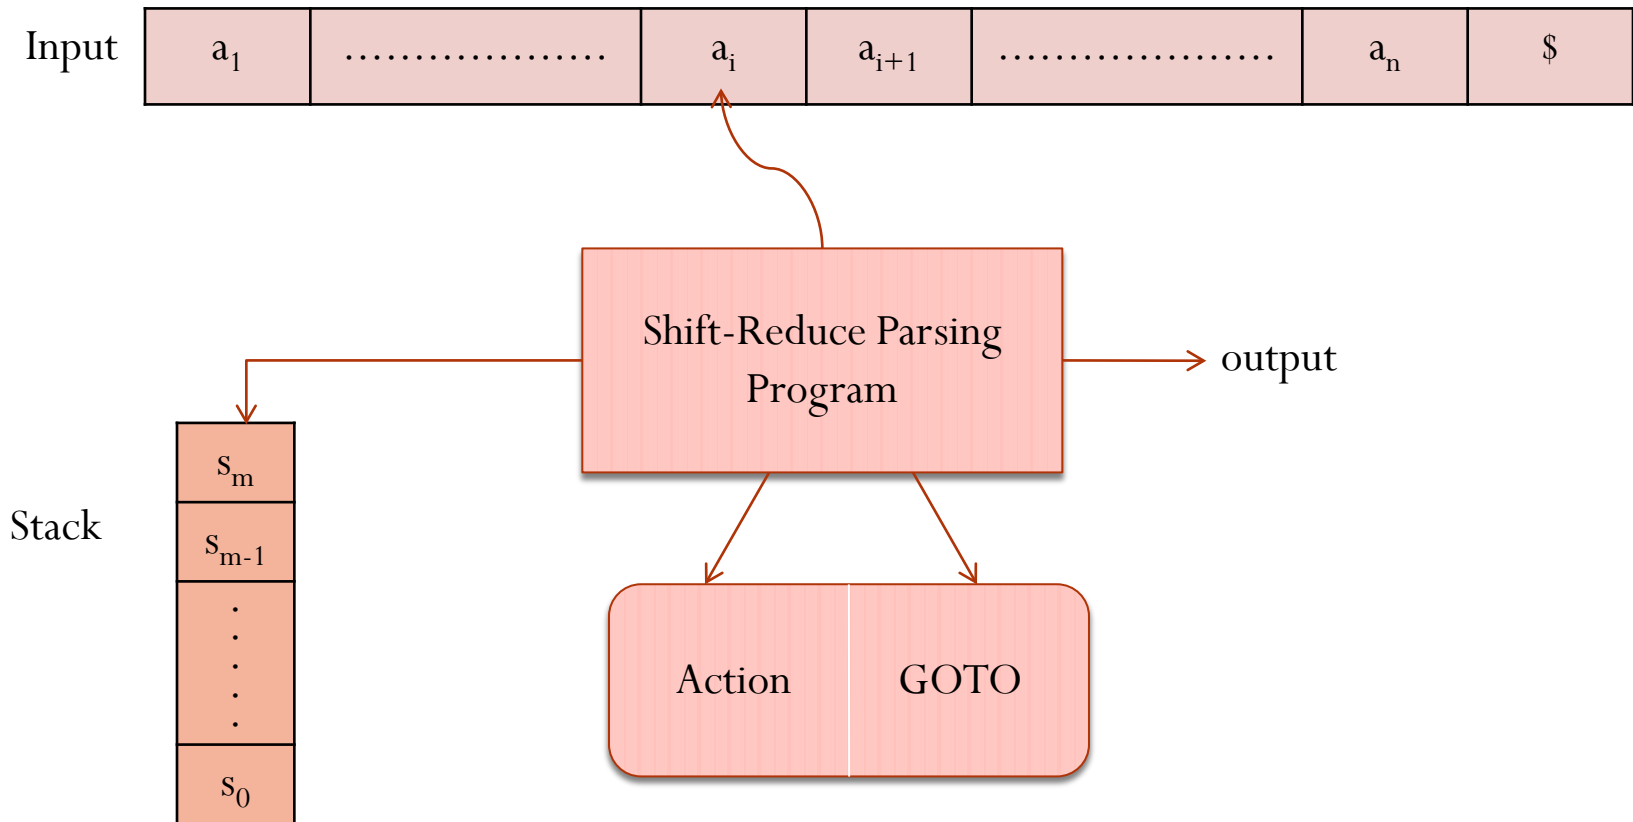

1. $S' \rightarrow S$
2. $S \rightarrow L = R$
3. $S \rightarrow R$
4. $L \rightarrow * R$
5. $L \rightarrow \text{id}$
6. $R \rightarrow L$

LR(1) Parsing Example

Also try the algorithm
on the string $* id = id$.

Stack	Input	Action
0	id = * id \$	Shift-5 (Shift State 5, equivalently terminal id)
0 id 5	= * id \$	Reduce-5 (Reduce using Rule-5, $L \rightarrow id$). Pop id. Push L which is equivalent to pushing GOTO(0, L)
0 L 2	= * id \$	Shift-6 (Shift =)
0 L 2 = 6	* id \$	Shift-11 (Shift *)
0 L 2 = 6 * 11	id \$	Shift-12 (Shift id)
0 L 2 = 6 * 11 id 12	\$	Reduce-5 (Reduce using Rule 5, $L \rightarrow id$). Pop id. Push L which is equivalent to pushing GOTO(11, L)
0 L 2 = 6 * 11 L 10	\$	Reduce-6 (Reduce using Rule 6, $R \rightarrow L$). Pop L. Push R which is equivalent to pushing GOTO(11, R)
0 L 2 = 6 * 11 R 13	\$	Reduce-5 (Reduce using Rule 5, $L \rightarrow * R$). Pop *R. Push L which is equivalent to pushing GOTO(6, L)
0 L 2 = 6 L 10	\$	Reduce-6 (Reduce using Rule 6, $R \rightarrow L$). Pop L. Push R which is equivalent to pushing GOTO(6, R)
0 L 2 = 6 R 9	\$	Reduce-2 (Reduce using Rule, $S \rightarrow L = R$ Pop $L = R$. Push S which is equivalent to pushing GOTO(0, S)
0 S 1	\$	Accept

LR Parsing Algorithm

- **LR Parser Configuration:** $(s_0 s_1 \dots s_m, a_i a_{i+1} \dots a_n \$)$
- This configuration represents the right-sentential form $X_1 X_2 \dots X_m a_i a_{i+1} \dots a_n$ where X_i is the transition label from the state s_{i-1} to s_i .

Behavior of the Parser

Current Configuration: $(s_0s_1 \dots s_m, a_ia_{i+1} \dots a_n\$)$

1. If $\text{ACTION}[s_m, a_i] = \text{shift } s$, then the next configuration is

$$(s_0s_1 \dots s_ms, a_{i+1} \dots a_n\$)$$

Remark: This is equivalent to shifting the terminal symbol a_i as the transition arc (s_m, s) is labeled a_i .

2. If $\text{ACTION}[s_m, a_i] = \text{Reduce } A \rightarrow \beta$, then

- a) Pop $r = |\beta|$ states from the stack and enter the intermediate configuration $(s_0s_1 \dots s_{m-r}, a_ia_{i+1} \dots a_n\$)$.

- b) Shift state s onto the stack where $\text{GOTO}(s_{m-r}, A) = s$

Final Configuration: $(s_0s_1 \dots s_{m-r}s, a_ia_{i+1} \dots a_n\$)$.

3. If $\text{ACTION}[s_m, a_i] = \text{accept}$, accept the input string.
4. If $\text{ACTION}[s_m, a_i] = \text{error}$, declare error and call an error recovery routine.

LR Parsing Algorithm

Let a be the first symbol of $w\$$

while(1) { /* repeat forever */

 Let s be the state on top of the stack;

 if (ACTION[s, a] = shift t) {

- a) push t onto the stack;
- b) let a be the next input symbol

 }

 else {

 if (ACTION[s, a] = reduce $A \rightarrow \beta$) {

- a) pop $|\beta|$ symbols off the stack;
- b) let state t now be on top of the stack;
- c) push GOTO[t, A] onto the stack;

 }

 else {

 if (ACTION[s, a] = accept) { print ACCEPT; break; }

 else { call error-recovery routine; }

 }

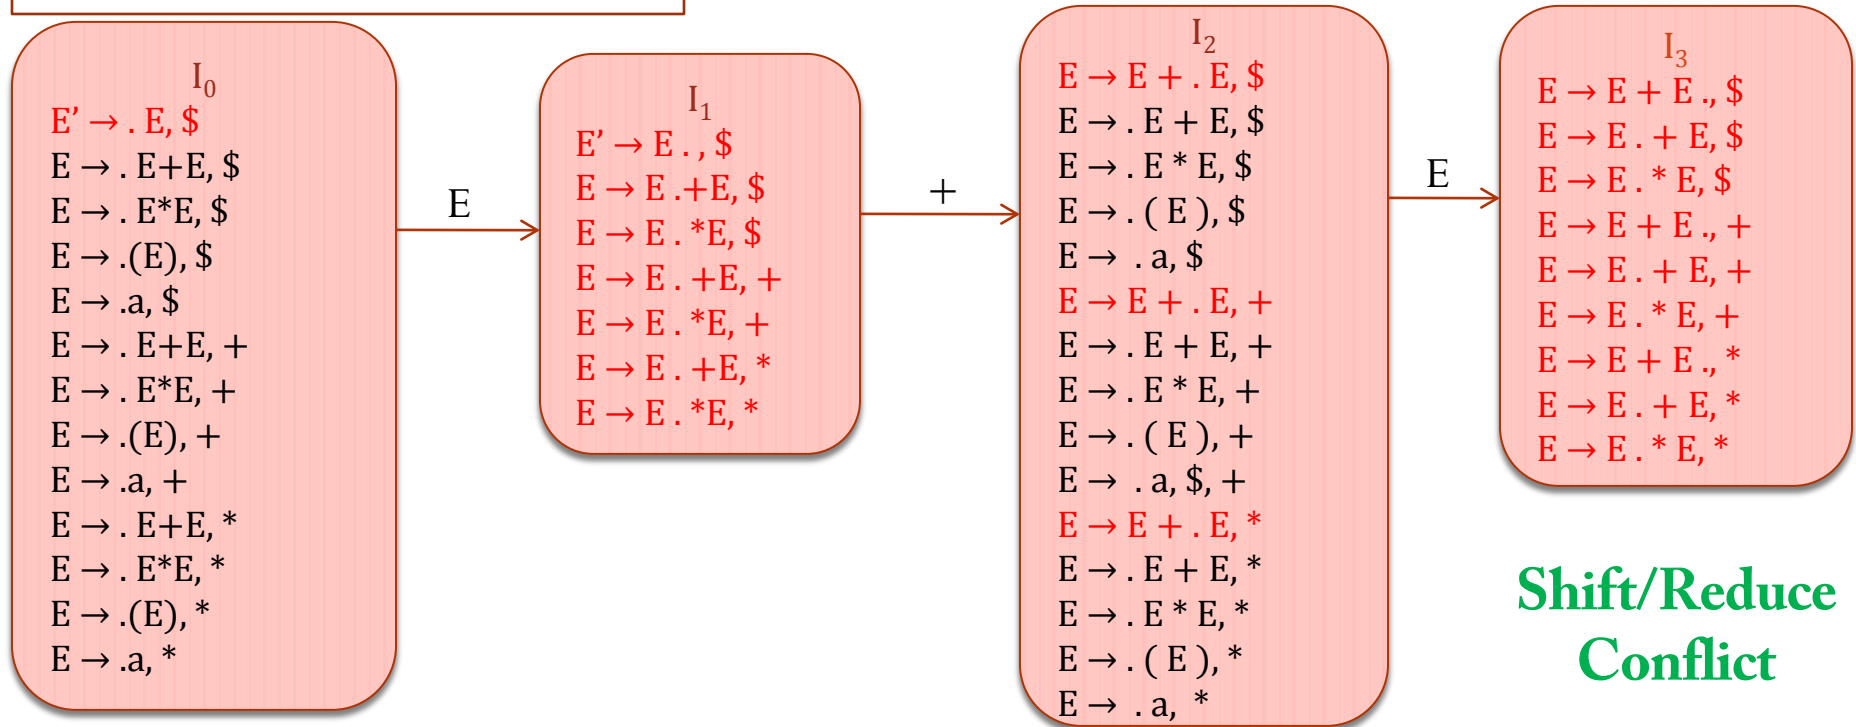

}

}

Handling Precedence and Associativity Rules

$E \rightarrow E + E \mid E * E \mid (E) \mid a$

Partial LR(1) Automaton

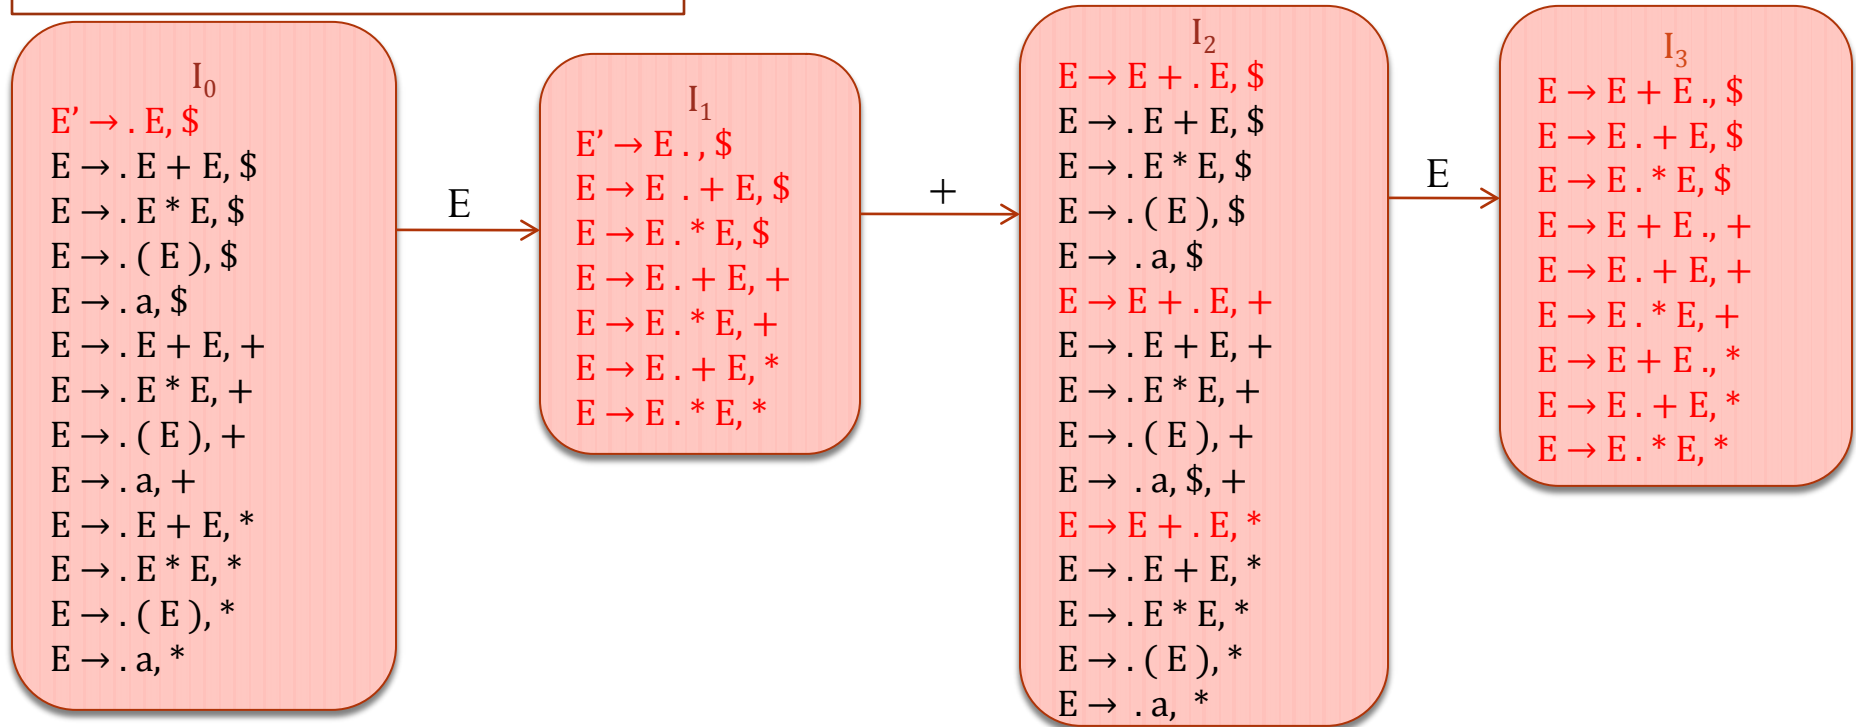

Q: If the state on the top of the parser stack is 3 and the next input symbol is +, should the parser perform a shift action or a reduce action?

- Perform reduce action if we want to make + left-associativity operation.
- Perform shift action if we want to make + right-associative.

Handling Precedence and Associativity Rules

$E \rightarrow E + E \mid E * E \mid (E) \mid a$

Partial LR(1) Automaton

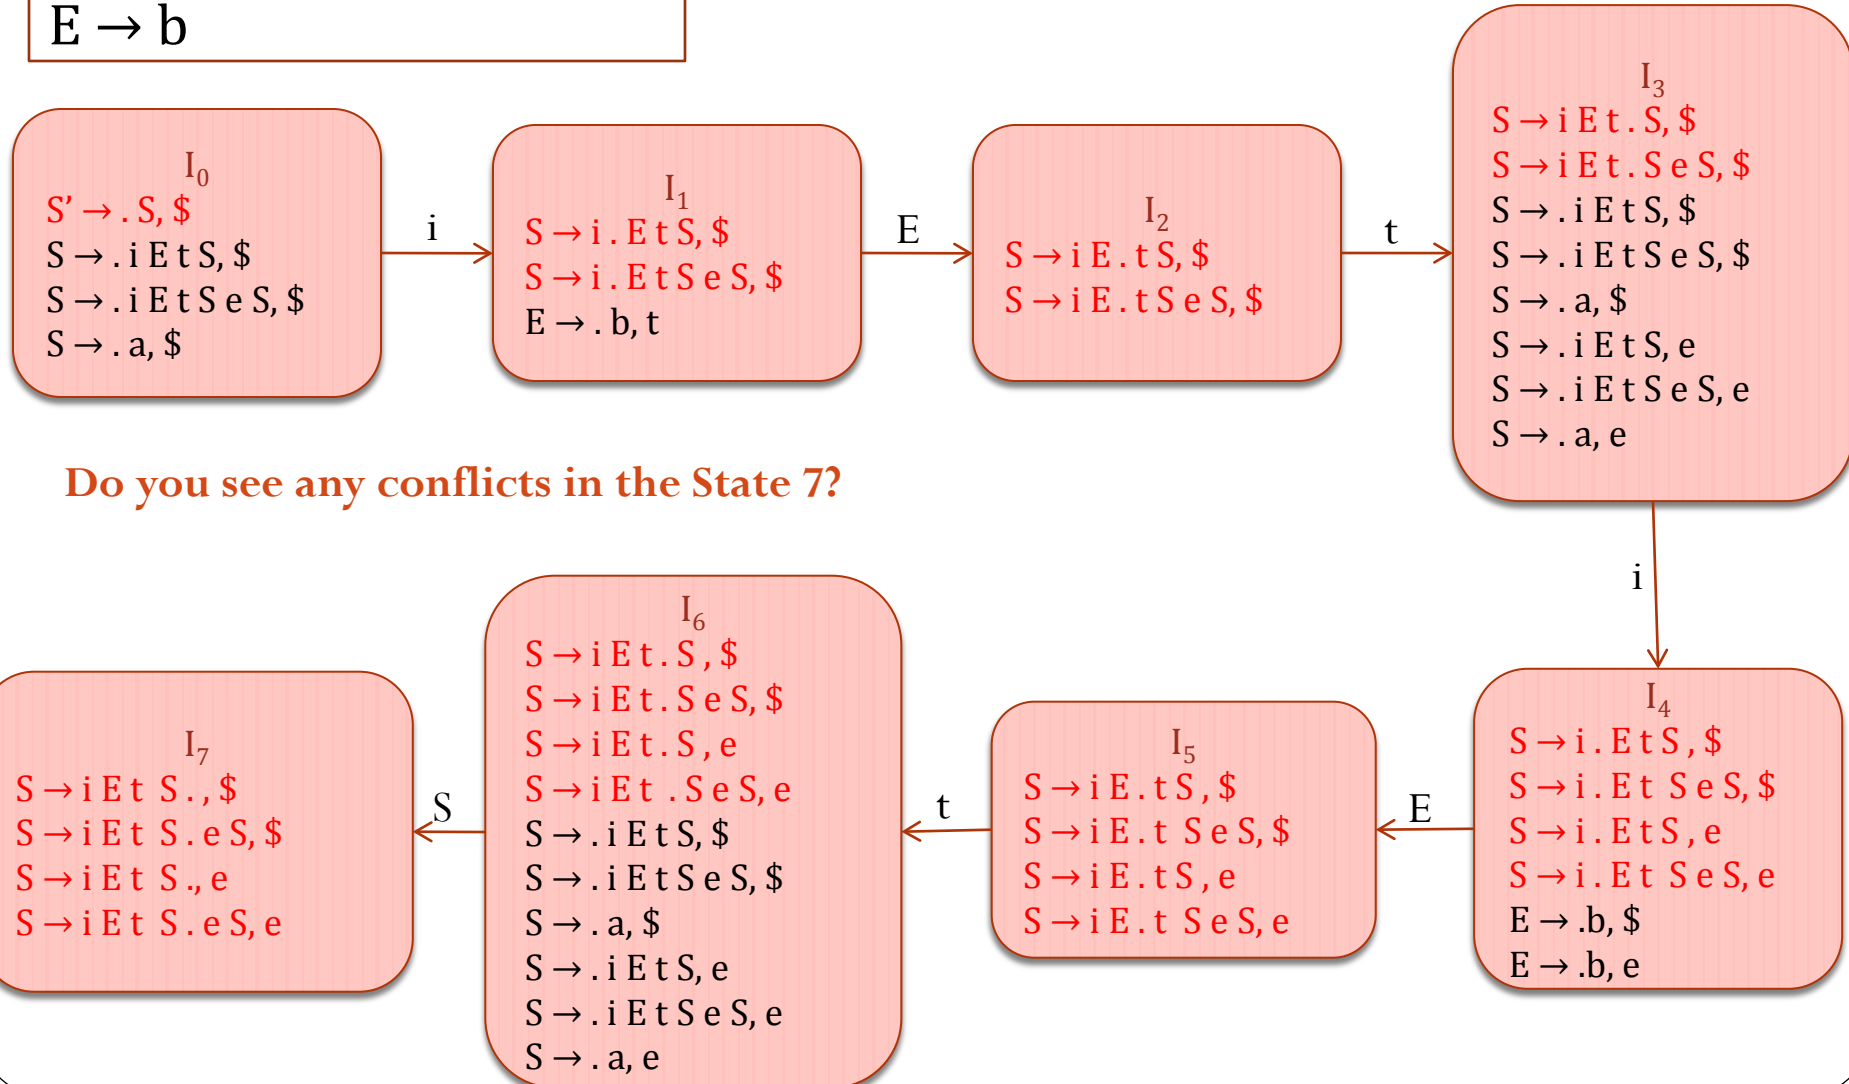

Q: If the state on the top of the parser stack is 3 and the next input symbol is $*$, should the parser perform a shift action or a reduce action?

- Perform reduce action if we want to make $\text{Prec}(+) > \text{Prec}(*)$
- Perform shift action if we want to make $\text{Prec}(+) < \text{Prec}(*)$

Handling if-then-else ambiguity

$$S \rightarrow iEtS \mid iEtSeS \mid a$$
$$E \rightarrow b$$

Partial LR(1) Automaton

Do you see any conflicts in the State 7?

LALR(1) Grammars

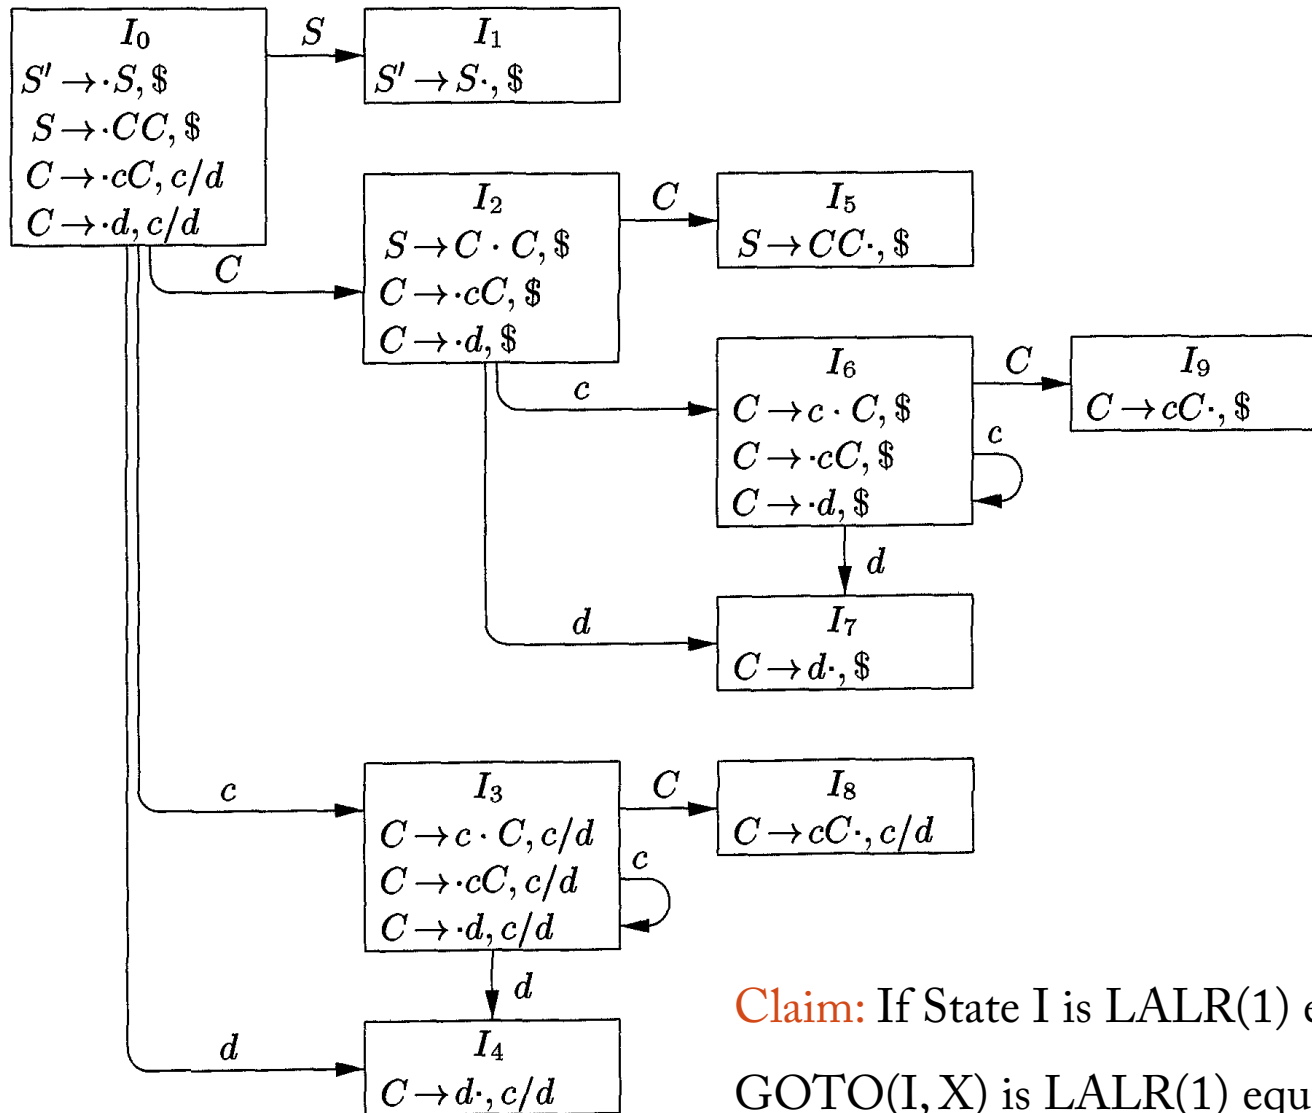

LALR(1) Grammars

- LR(1) automaton for a C-like programming language could have thousands of states.
 - Huge parsing table.
- **LALR(1) Approach:** If two states have kernels whose first elements are same merge them.

$$\begin{bmatrix} [S \rightarrow id, +] \\ [S \rightarrow E., \$] \end{bmatrix} + \begin{bmatrix} [S \rightarrow id, \$] \\ [S \rightarrow E., +] \end{bmatrix} = \begin{bmatrix} [S \rightarrow id, +] \\ [S \rightarrow id, \$] \\ [S \rightarrow E., +] \\ [S \rightarrow E., \$] \end{bmatrix}$$

- LALR(1) Table Compaction Approach can reduce the number of LR(1) states from thousands to hundreds.

LALR(1) Grammars

S'	\rightarrow	S
S	\rightarrow	$C C$
C	\rightarrow	$c C \mid d$

Merge

1. States 4 and 7.
2. States 3 and 6.
3. States 8 and 9.

Claim: If State I is LALR(1) equivalent to State J, then $\text{GOTO}(I, X)$ is LALR(1) equivalent to $\text{GOTO}(J, X)$.

LALR(1) Grammars

LR(1) Parsing Table

STATE	ACTION			GOTO	
	<i>c</i>	<i>d</i>	\$	<i>S</i>	<i>C</i>
0	s3	s4		1	2
1			acc		
2	s6	s7			5
3	s3	s4			8
4	r3	r3			
5			r1		
6	s6	s7			9
7			r3		
8	r2	r2			
9			r2		

LALR(1) Grammars

LALR(1) Parsing Table

STATE	ACTION			GOTO	
	<i>c</i>	<i>d</i>	\$	<i>S</i>	<i>C</i>
0	s36	s47		1	2
1			acc		
2	s36	s47			5
36	s36	s47			89
47	r3	r3	r3		
5			r1		
89	r2	r2	r2		

LALR(1) Grammars

- A Grammar is said to be LALR(1) if after merging states in LR(1) automaton no conflicts arise.
- When a LALR(1) automaton is constructed from LR(1) automaton, we can only expect to see Reduce-Reduce conflicts but not Shift-Reduce conflicts. Why?

S'	\rightarrow	S
S	\rightarrow	$a A d \mid b B d \mid a B e \mid b A e$
A	\rightarrow	c
B	\rightarrow	c

$\{[A \rightarrow c\cdot, d], [B \rightarrow c\cdot, e]\}$

$\{[A \rightarrow c\cdot, e], [B \rightarrow c\cdot, d]\}$

- **Final Remark:** In Practice LALR(1) suffice for our purposes.
